

# CO<sub>2</sub> Capture by Ionic Liquids – An Answer to Anthropogenic CO<sub>2</sub> Emissions?

Pauline Sanglard<sup>a</sup>, Olivier Vorlet<sup>a</sup>, Roger Marti<sup>a</sup>, Olivier Naef<sup>fb</sup>, and Ennio Vanoli<sup>\*,a</sup>

**Abstract:** Ionic liquids (ILs) are efficient solvents for the selective removal of CO<sub>2</sub> from flue gas. Conventional, off-the-shelf ILs are limited in use to physisorption, which restricts their absorption capacity. After adding a chemical functionality like amines or alcohols, absorption of CO<sub>2</sub> occurs mainly by chemisorption. This greatly enhances CO<sub>2</sub> absorption and makes ILs suitable for potential industrial applications. By carefully choosing the anion and the cation of the IL, equimolar absorption of CO<sub>2</sub> is possible. This paper reviews the current state of the art of CO<sub>2</sub> capture by ILs and presents the current research in this field performed at the ChemTech Institute of the Ecole d'Ingénieurs et d'Architectes de Fribourg.

**Keywords:** Carbon dioxide · Capture · Chemisorption · Ionic liquids · Physisorption

## Introduction

The level of CO<sub>2</sub> in the atmosphere is rising dramatically, reaching for the first time in May 2013 the level of 400 ppm in Mauna Loa (Hawaii) (Fig. 1).<sup>[1]</sup> Thus a great effort is made to find solutions to reduce greenhouse gas (GHG) emissions and especially its major contributor, CO<sub>2</sub>. Industries and transport are the major segments responsible for GHG emissions in Switzerland (Fig. 2) with 11.2 million tonnes CO<sub>2</sub> equivalents in 2007.<sup>[2]</sup>

Three basic possibilities exist to mitigate anthropogenic CO<sub>2</sub> emissions: reducing them at the source, sequestering CO<sub>2</sub> or utilizing CO<sub>2</sub>. Carbon capture and sequestration (CCS) technologies can be used to stock the captured CO<sub>2</sub>, for example in geological systems.<sup>[3]</sup> Instead of treating CO<sub>2</sub> as a waste, it can also be considered as a chemical raw material. For example it can be recycled in the food industry or used as chemical feedstock in the synthesis of chemicals (urea, salicylic acid, cyclic carbonates).<sup>[4]</sup> This approach is known as carbon capture and utilization (CCU) and it is the most promising and energetically 'useful' approach.

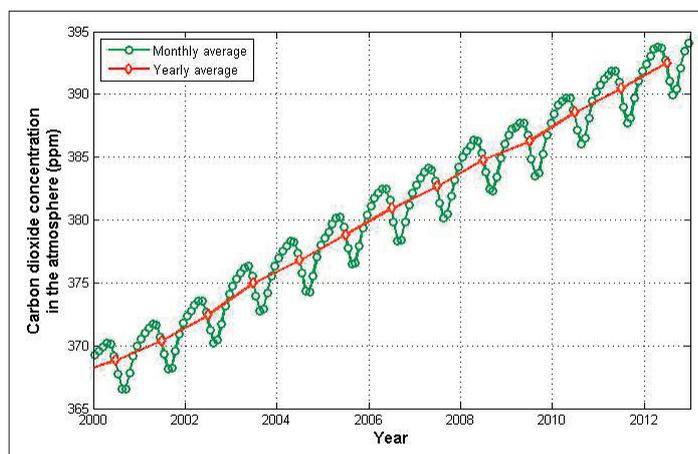

Fig. 1. Evolution of the global CO<sub>2</sub> concentration in the atmosphere.<sup>[1]</sup>

Current technologies available on the market to remove CO<sub>2</sub> from flue gas are based on amine solutions such as monoethanolamine (MEA), diethylamine (DEA) or methyldiethanolamine (MDEA), whereby primary amines react with CO<sub>2</sub> forming a carbamate by a 2:1 stoichiometry (Scheme 1). Table 1 presents an overview of commercial solutions. For example the FLUOR process is used to capture 330 tonnes per day at the Bellingham Energy

center (USA) and the captured CO<sub>2</sub> is recycled in the food industry.

The drawbacks of aqueous amine technologies are their corrosivity, degradation, and energy cost for regeneration due to the water present in the system.<sup>[13]</sup> Furthermore, they can degrade to nitrosamines, which are known to be carcinogenic.<sup>[14]</sup>

ILs are organic salts with melting points typically below 100 °C. ILs have

recently proven to be efficient media for the capture of acidic gases such as carbon dioxide or hydrogen sulfide.<sup>[15–18]</sup> Their negligible vapor pressure and their stability offer a strong advantage compared to the amine solutions currently used in the flue gas treatment industry.

The use of ILs ensures no contamination of the treated gas as well as no loss of the ILs by evaporation. Moreover, by tuning their anion and cation, one is able to design their physical and chemical properties such as corrosivity, viscosity and, above all, their CO<sub>2</sub> absorption capacity, which makes ILs ideal sorbents for any industrial applications.

This review focuses on the capture of CO<sub>2</sub> by ILs. The steric and electronic effects and the influence of the anion and cation on the absorption capacity will be discussed.

## Absorption of CO<sub>2</sub> by Ionic Liquids

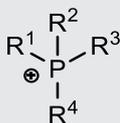

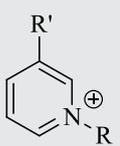

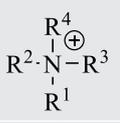

### Literature Review Physiosorption

Many research groups are active in the field of CO<sub>2</sub> capture by ionic liquids. Commercial, off-the-shelf ILs (Fig. 3) usually show rather poor absorption capacities. There is no task-specific CO<sub>2</sub> binding, resulting in processes where only physiosorption occurs, meaning ‘simple’ dissolving CO<sub>2</sub> in the IL. The solubility of CO<sub>2</sub> in those ILs is comparable to conventional solvents (Table 2) with Henry’s constants (H) around 30–70 bar, which correspond

Table 2. Henry’s constants (H) for the solubility of CO<sub>2</sub> in ionic liquids and solvents.

to a solubility of 0.01–0.03 mol CO<sub>2</sub> per mol solvent.

Henry's law is represented in Eqn. (1) where *p* is the partial pressure of the gas above the solution and *x* the molar fraction of the gas in the solution.

$$H = \frac{p}{x} \quad (1)$$

A low Henry's constant means a high solubility and vice versa. High pressure of CO<sub>2</sub> or low temperature is therefore needed to achieve significant absorption with those ILs.

Absorption by conventional imidazolium-based ILs is well described in the literature. Studies show that the solubility tends to rise with the increase of the alkyl chain on the imidazolium<sup>[19]</sup> because of the gain of free volume within the molecule.

It has been found that carbon dioxide solubility in the ionic liquids depends more on the nature of the anion than on the cation,<sup>[16,28]</sup> mainly because of the intrinsic basic nature of the anion.<sup>[30]</sup> The affinity of CO<sub>2</sub> for the anion follows the order:<sup>[21]</sup> [BF<sub>4</sub>]<sup>-</sup> < [TfO]<sup>-</sup> < [B(CN)<sub>4</sub>]<sup>-</sup> ≈ [Tf<sub>2</sub>N]<sup>-</sup> < [pFAP]<sup>-</sup> with a factor of roughly 3 between [BF<sub>4</sub>]<sup>-</sup> and [pFAP]<sup>-</sup>. This illustrates that fluorination of the anion increases the CO<sub>2</sub> solubility. However, the fluorinated groups raise environmental concerns because of their toxicity.<sup>[17]</sup> Fluorinated anions can also decompose into HF in the presence of water, making them unsuitable for large industrial applications, as well as being pricey.

ILs limited to absorption of CO<sub>2</sub> solely by physisorption are unable to compete with aqueous amines (Henry constant of *H* = 3.16 bar for MEA). Thus, adding functional groups to the IL that can 'react' with CO<sub>2</sub> increases absorption because it leads to chemisorption instead of physisorption.

### Chemisorption

Various strategies have been developed to enhance the CO<sub>2</sub> absorption capacity by functionalization of ILs. The advantage of task-specific ionic liquids (ionic liquids functionalized for specific applications) is that by attaching an additional functionality capable of linking to CO<sub>2</sub>, one moves from physisorption to chemisorption. A literature summary of absorption capacities of various task-specific ILs is presented in Table 3.

To compete with aqueous amines, ILs should not only have a higher absorption capacity but also a low molecular weight, limiting the amount of IL needed for an industrial process of CO<sub>2</sub> removal. In the next paragraphs we will discuss three different strategies to chemically absorb CO<sub>2</sub>.  
**Switchable Liquids**

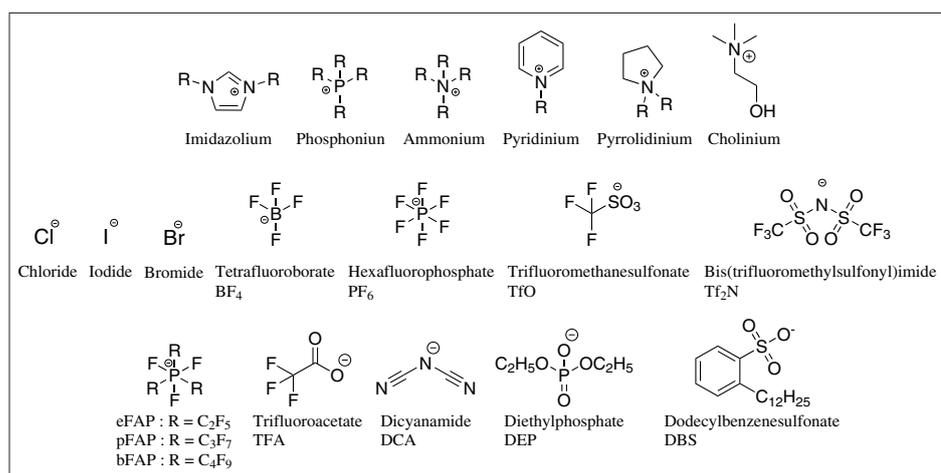

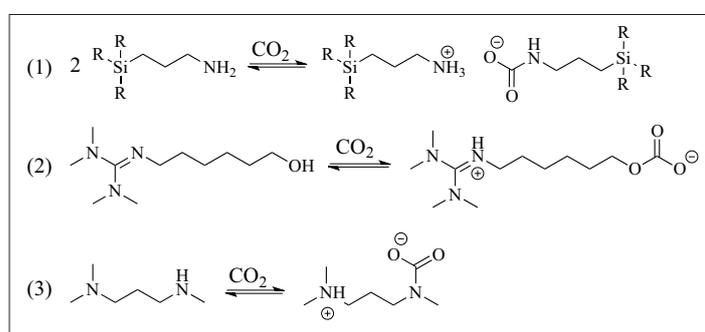

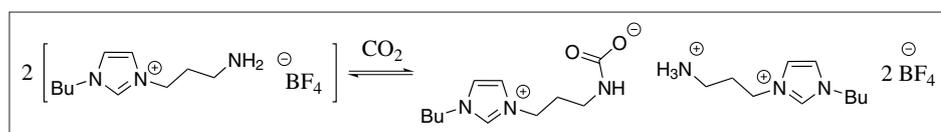

Fig. 3. Common cations and anions of ionic liquids.

Scheme 2. Reversible ILs formed by bubbling CO<sub>2</sub> through molecular liquids: (1) trialkylsilamines, (2) alkanol guanidines and (3) diamines.Scheme 3. Reaction of CO<sub>2</sub> capture by an amine functionalized imidazolium.<sup>[33]</sup>

A special type of liquid chemically binds to CO<sub>2</sub> forming salts or molten salts. This phenomenon is reversible upon heating to desorb the CO<sub>2</sub>. Trialkylsilamines have this property to form reversible ILs in contact with CO<sub>2</sub>.<sup>[45]</sup> Two molecules of this compound are required to catch one molecule of CO<sub>2</sub>. On the other hand, alkanol guanidines, alkanol amidines and diamines react with CO<sub>2</sub> to form zwitterions.<sup>[46]</sup> The zwitterionic form has the advantage to follow a 1:1 mechanism (Scheme 2) – thus an equimolar absorption of CO<sub>2</sub>.

#### Functionalization of Cation

Bates *et al.*<sup>[33]</sup> were the first to propose to functionalize ILs with an amine to increase the capacity. They added a primary amine moiety to an imidazolium cation. They reached an absorption of 0.5 mol CO<sub>2</sub>/mol IL for their aminopropylbutylimidazolium tetrafluoroborate, which is the stoichiometric maximum because two amines are necessary to catch one CO<sub>2</sub> molecule (Scheme 3). But they reported a high viscosity for their ionic liquid. Other researchers added an ether moiety to the imidazolium cation with common anions

and obtained absorption up to 1 mol CO<sub>2</sub>/mol IL.<sup>[31]</sup> In this case, the lone pair of the oxygen atom on the imidazolium attacks the carbon of the CO<sub>2</sub> to form a carboxylic acid.

Xue *et al.*<sup>[32]</sup> also functionalized an imidazolium cation with an amine but they used taurine as an anion. They obtained absorption of up to 0.9 mole of CO<sub>2</sub> for one mole of IL – but they also reported high viscosity of the IL-CO<sub>2</sub> compounds. Zhang *et al.*<sup>[39]</sup> functionalized both the cation and the anion by amines. They synthesized a series of 20 ionic liquids with amino acid anions and an amino-functionalized phosphonium cation. To overcome the issue of high viscosity, they supported the ILs on SiO<sub>2</sub>. Using this approach, absorptions close to equimolar were reached.

#### Functionalization of Anion

By adding the functional group to the anion, a 1:1 mechanism is theoretically possible.<sup>[47]</sup> Wang *et al.*<sup>[41]</sup> developed ionic liquids with a phosphonium cation and phenols as anions (Scheme 4) – with this IL, absorption of 0.9 mol CO<sub>2</sub>/mol IL at 30°C was reached. The position of the substituent on the phenolic ring significantly influences the viscosity of the IL. The electronic nature, the position and the number of the substituents affect strongly the CO<sub>2</sub> absorption capacity. The researchers also observed a linear relationship between the pK<sub>a</sub> of the phenolic anion (PhO) and the absorption capacity of the IL.

The same research group<sup>[40]</sup> studied the influence of the basicity of the anion on the absorption of CO<sub>2</sub> (Fig. 4). This strategy takes advantage of the acidity of the CO<sub>2</sub> and the inherent basicity of the anion. They discovered a linear relationship between the pKa of the anion and the enthalpy of absorption. The anion with the lowest pKa (tetrazolide, 8.2 in DMSO) and the highest pKa (pyrazolide, 19.8 in DMSO) showed, respectively, an absorption enthalpy of 19.1 kJ/mol and 89.9 kJ/mol and absorption capacities of 0.08 mol CO<sub>2</sub>/mol IL and 1.02 mol CO<sub>2</sub>/mol IL. A high enthalpy of absorption means more difficult desorption. They identified triazolide as an ideal anion, which showed good absorption of 0.95 mol CO<sub>2</sub>/mol IL and a relatively low absorption enthalpy of 56 kJ/mol. Moreover triazolides are aprotic, inhibiting the formation of hydrogen bonds that are responsible for an increase in viscosity during CO<sub>2</sub> absorption.

Wang *et al.*<sup>[44]</sup> also developed ILs with superbase cations that provide the thermodynamic driving force for the protic anion to react with CO<sub>2</sub>. They obtained equimolar absorption for [MTBDH][trifluoroethanol] and [MTBDH][imidazole] and up to 2 mol CO<sub>2</sub>/mol IL for [MTBDH][hexafluoropentanediol].

A strong effort has been made to develop ILs from 'green' sustainable sources. Zhang *et al.*<sup>[43]</sup> synthesized a series of amino acid-based ILs (AAILs) with tetrabutylphosphonium as cation. Because of their high viscosity, they supported the AAILs on silica gel or added small amounts of water. The absorption capacities of the supported AAILs were between 0.6 and 0.7 mol CO<sub>2</sub>/mol IL and close to 1 mol CO<sub>2</sub>/mol IL for the AAILs with water. They suggested that for supported AAILs, the proportion of captured CO<sub>2</sub> higher than 0.5 mol CO<sub>2</sub>/mol IL is due to physisorption. They observed a white precipitate when water was present. They proposed a mechanism based on analytical investigations showing that the white precipitate is the zwitterionic form of the amino acid. Gurkan *et al.*<sup>[48]</sup> contested the 1:2 mechanism and favored the 1:1 mechanism based on molecular simulations (Scheme 5).

Goodrich *et al.*<sup>[38]</sup> obtained experimental values of absorption for different AAILs slightly lower than 1 mol CO<sub>2</sub>/mol IL. To explain this behavior they assumed a competition between a 1:2 mechanism and a 1:1 mechanism, the 1:2 being less favorable.

Moreover, by capturing CO<sub>2</sub>, the viscosity increases further<sup>[49]</sup> due to the hydrogen bonding network being formed, which slows the dynamics of absorption.<sup>[50]</sup> Gurkan *et al.*<sup>[42]</sup> addressed the problem of high viscosity by designing aprotic heterocyclic anions that suppress the formation of

the hydrogen bond network when capturing CO<sub>2</sub>. Anions such as 2-cyanopyrrolide or 3-(trifluoromethyl)pyrazolide (Fig. 5) have been proposed and showed capacities of absorption of 0.89 mol CO<sub>2</sub>/mol IL and 0.92 mol CO<sub>2</sub>/mol IL, respectively, with a trihexyltetradecylphosphonium cation.

Ma *et al.*<sup>[51]</sup> prepared ditetraalkylammonium amino acids ILs and dissolved them in water for CO<sub>2</sub> absorption measurement. The 20% solution showed the highest solubility of 0.66 mole CO<sub>2</sub> per mole anion (glycine).

Other polymerized ionic liquids were functionalized with methacrylate or vinylbenzyl. By this method Henry's constant was lowered from 59 bar for [bmim][BF<sub>4</sub>]<sup>[22]</sup> to 37.7 bar for polymeric [MABI][BF<sub>4</sub>] and 26.0 bar for polymeric [VBBI][BF<sub>4</sub>].<sup>[52]</sup>

Using carboxylic anions is another possibility that decreases the Henry's constant to 13 bar for [emim][OAc] at 30°C.<sup>[21]</sup>

## Research at the EIA-FR

The ChemTech Institute is active in the development of a green industrial process to remove CO<sub>2</sub> from flue gas or air. The goal is to absorb CO<sub>2</sub> in an ionic liquid and then use it to synthesize chemicals.

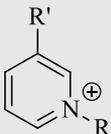

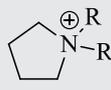

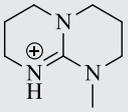

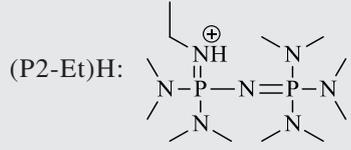

We adapted a stoichiometric method<sup>[53]</sup> to characterize the absorption of CO<sub>2</sub> in our synthesized ILs. A tightly closed vial with a precise volume placed in a thermostated bath is filled with CO<sub>2</sub> at atmospheric pressure. A known amount of IL is then injected in the vial and the pressure is monitored. The absorption capacity is calculated from the pressure difference by the ideal gas law (Eqn (2)).

$$n_{CO_2} = \frac{pV}{RT} \quad (2)$$

First we screened different anions with trihexyltetradecylphosphonium (P66614) and propylmethylimidazolium (PrMIM) cations (Table 4).

The 2-cyano-Pyr anion is the most promising because of its low viscosity and good absorption properties (0.9 mol CO<sub>2</sub>/mol IL). However, its price is prohibitive for large scale applications. Amino acid anions showed very good absorption capacities but high viscosities. Nevertheless, their renewability and easy availability made us pursue our efforts in this direction. To obtain 'green' ILs, we switched to the cation cholinium (Cho). Cho is available on large scale as an additive in chicken feed and it is relatively cheap. Choline combined to amino acids give 'green' ILs with good absorption properties. But their

high viscosity is a major drawback and it increases further when absorbing CO<sub>2</sub>. As described by Zhang *et al.*<sup>[43]</sup> we observed also a white precipitate during absorption with AAILs when water was present in the system.

*Para*-methoxy-phenol (*p*-methoxy-PhO) seems to be a more suitable anion: the increase in viscosity during absorption is less pronounced. Furthermore phenolates do not give rise to the problem of precipitation in the presence of water – amino acids form zwitterions when water is present during absorption (Scheme 5). The recyclability of [Cho][*p*-methoxy-PhO] was tested in the presence of PEG 400 to reduce the viscosity (Fig. 6). After the second cycle, the absorption capacity stabilized itself slightly higher than 0.7 mol CO<sub>2</sub>/mol IL and did not change for the seven following cycles. A good recyclability of the IL upon absorption–desorption is crucial for a CCU process. CO<sub>2</sub> should be quantitatively recovered to be used as a chemical starting material and to retain the activity of the IL.

Furthermore, the relatively low molecular mass of Cho (compared to phosphonium or imidazolium) provides low molar weight ILs, thus high mass absorption capacities.

Scheme 4. Capture of CO<sub>2</sub> by substituted phenolic ionic liquids.

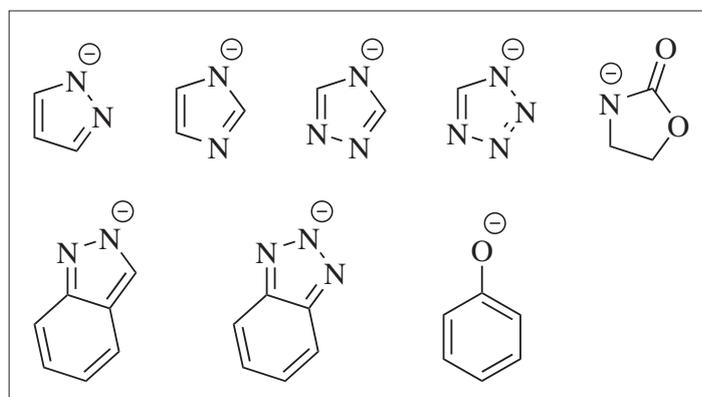

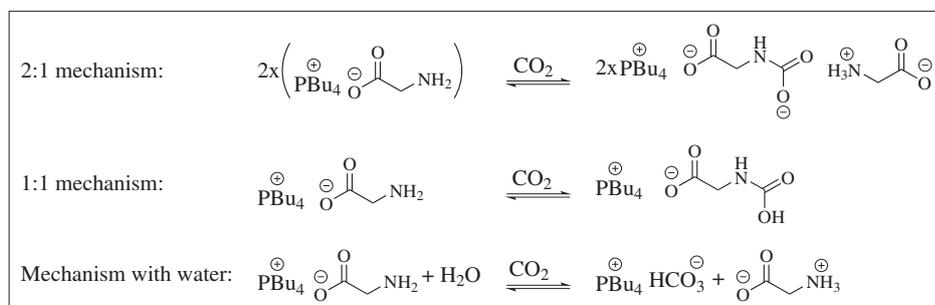

Fig. 4. Basic anions studied. From left to right and top to bottom: pyrazolide, imidazolidide, triazolide, tetrazolide, 2-oxooxazolidinide, indazolide, benzotriazolide and phenolate.

Scheme 5. Reaction of absorption of CO<sub>2</sub> by [PBu<sub>4</sub>][Gly] following a 2:1 mechanism, a 1:1 mechanism and the mechanism when the IL contains water.

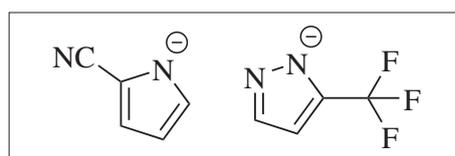

Fig. 5. Structures of 2-cyanopyrrolide and 3-(trifluoromethyl)pyrazolide.

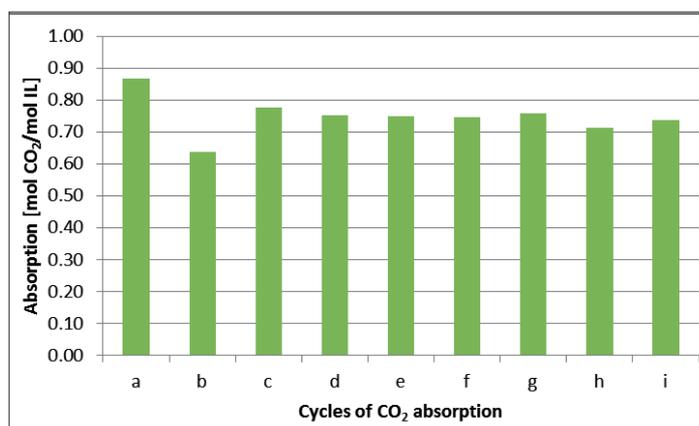

Fig. 6. Cycles of absorption of CO<sub>2</sub> in [Cho][4-MeO-PhOH] 33% in PEG.

## Conclusion

Task-specific ionic liquids are efficient media for CO<sub>2</sub> capture – especially anion-

functionalized ionic liquids. However, their viscosity can be an issue, particularly because it further increases upon binding with CO<sub>2</sub>. Thus, efforts have to be contin-

ued in order to design low viscosity ionic liquids. Selectivity of ionic liquids to CO<sub>2</sub> should not be ignored – H<sub>2</sub>S will compete with CO<sub>2</sub> if present.<sup>[54]</sup> Toxicity of the IL should also be taken into account.<sup>[55]</sup> However by carefully designing the anion and the cation, it is feasible to optimize the ILs in terms of toxicity, efficacy of CO<sub>2</sub> capture and viscosity which makes them promising solvents for industrial applications of CO<sub>2</sub> removal.

We developed green, cheap ionic liquids that absorb up to 1 mol CO<sub>2</sub> per mol IL. Moreover our ILs show a good recyclability upon absorption–desorption.
